Phosphoinositide 3-kinase in Health and Disease. PI3K has become a very intense area of research, with over 2000 publications on PI3K in PubMed for 2009 alone. The expectations for a therapeutic impact of intervention with PI3K activity are high, and progress in the clinical arena is being closely monitored; however, targeted therapies almost invariably encounter roadblocks, often exposing unresolved questions in the basic understanding of the target.

Phosphoinositide 3-kinases (PI3Ks), also called phosphatidylinositol 3-kinases, are a family of enzymes involved in cellular functions such as cell growth, proliferation, differentiation, motility, survival and intracellular trafficking, which in turn are involved in cancer.

A phosphoinositide 3-kinase inhibitor (PI3K inhibitor) is a class of medical drug that functions by inhibiting one or more of the phosphoinositide 3-kinase enzymes, which are part of the PI3K/AKT/mTOR pathway, an important signalling pathway for many cellular functions such as growth control, metabolism and translation initiation.

To study the role of phosphoinositide 3-kinase (PI3K) signaling in pericyte biology during angiogenesis, we used genetic mouse models that allow selective inactivation of PI3K α and PI3K β isoforms and their negative regulator phosphatase and tensin homolog deleted on chromosome 10 (PTEN) in mural cells.

It has been reported that the phosphorylation status of phosphoinositide 3-kinase (PI3K) and its target AKT (protein kinase B) prevent the spermatozoon from entering the truncated apoptotic cascade. Here, we aim to study the regulation of the PI3K/AKT pathway by PRDX6 and assess its role in maintaining sperm viability.

PI3Ks are lipid kinases that phosphorylate the 3'-OH group of the inositol ring in membrane phospholipids to generate intracellular second messengers (reviewed in Refs. 29–31). The preferred inositol-containing substrate in intact cells is phosphatidylinositol 4,5-bisphosphate which is converted to phosphatidylinositol 3,4,5-triphosphate.
